

The slide features a dark blue background. At the top left, an orange box contains the text 'MODULE 10'. Below this, the title 'Basic Troubleshooting' is displayed in large white font. A line of orange text reads: 'Monday morning tickets: connection errors, login failures, and slow queries. Here is how to diagnose and resolve them confidently.' Below this text are three colored boxes: a red box labeled 'Connection Issues', an orange box labeled 'Login Failures', and a blue box labeled 'Error Logs'. At the bottom left, small white text indicates 'Day 2 · Afternoon · 1 hour' and 'Module 10: Basic Troubleshooting'. At the bottom right, '1 / 7' is shown.

Slide 1 of 7

Module 10: Basic Troubleshooting

Module	Day	Duration	Lab
10	2 — Afternoon	60 minutes	Lab 10

Monday morning support tickets follow predictable patterns: "I can't connect to SQL Server," "My login isn't working," or "the report is incredibly slow today." This module gives you a structured response to each of these common scenarios so you can diagnose the root cause quickly and resolve it with confidence.

You will learn to read the SQL Server Error Log — the most authoritative source of truth about what the engine has experienced — and to apply a disciplined first-response workflow to connection failures, authentication errors, and performance bottlenecks. The lab simulates three realistic support tickets.

Troubleshooting Is a Process, Not a Guess

Every troubleshooting session should follow the same pattern: (1) Reproduce the problem. (2) Identify the error message and its code. (3) Read the Error Log for details. (4) Isolate the layer

(network, service, authentication, query). (5) Fix the root cause — not just the symptom.

What This Module Covers

- **Connection Errors** Error 53, 17, 4060, 10060 — causes, diagnostics, and fixes.
- **Login Failures** Error 18456 state codes — what each state means and how to resolve it.
- **SQL Server Error Log** Reading the log in SSMS and via `sp_readerrorlog`.
- **Performance Bottlenecks** Six bottleneck categories and their first-response diagnostic queries.

What You Will Learn

By the end of Module 10 you will be able to:

-  Diagnose and resolve the most common SQL Server connection errors
-  Identify the root cause of login failure errors (18456 and variants)
-  Read the SQL Server Error Log in SSMS and via T-SQL
-  Apply a structured first-response workflow to an unfamiliar incident
-  Simulate and resolve three realistic Monday-morning support tickets

Module 10: Basic Troubleshooting

2 / 7

Slide 2 of 7

Learning Objectives

By the end of Module 10 you will be able to:

- **Diagnose and resolve the most common SQL Server connection errors** — error 53, 17, 4060, and 10060 with a structured check sequence.
- **Identify the root cause of login failure error 18456** — using the state code from the SQL Server Error Log, not the generic client message.
- **Read the SQL Server Error Log in SSMS and via T-SQL** — using `sp_readerrorlog` with keyword filters.
- **Apply a structured first-response workflow to performance incidents** — CPU, memory, I/O, lock, network, and query design bottlenecks.
- **Simulate and resolve three realistic Monday-morning support tickets** — connection failure, login failure, and slow query.

Common Connection Errors

Most connection failures have a small set of root causes — check them in order.

Error 53 — "Network path not found"

SQL Server Browser not running, or TCP/IP disabled.
Fix: SQL Server Configuration Manager → enable TCP/IP → restart service.
Check: telnet <server> 1433 or Test-NetConnection <server> -Port 1433

Error 17 — "SQL Server does not exist or access denied"

Instance name wrong, or firewall blocking port 1433.
Fix: Verify instance name (SERVERNAME or SERVERNAME\INSTANCENAME).
Check: Windows Firewall → Inbound Rule for TCP 1433 exists and is enabled.

Error 4060 — "Cannot open database requested"

Login is valid but default database is offline or dropped.
Fix: ALTER LOGIN [user] WITH DEFAULT_DATABASE = master;
Or: specify a different database in the connection string.

Error 10060 — "Connection timed out"

Network latency, wrong IP, or SQL Server not accepting connections.
Fix: ping the server, check IP/hostname, verify SQL Server is Running.
Check: sys.dm_exec_connections — if 0 rows, service may be down.

Module 10: Basic Troubleshooting

3 / 7

Slide 3 of 7

Common Connection Errors

Most connection failures trace back to a small set of root causes. Always check them in order: service status first, then network, then configuration, then authentication.

Error	Message (abbreviated)	Root Cause	First Fix
53	"Network path not found"	SQL Server Browser stopped, or TCP/IP disabled	Config Manager → enable TCP/IP → restart service
17	"SQL Server does not exist or access denied"	Wrong instance name, or firewall blocking port 1433	Verify instance name; check Windows Firewall inbound rule for TCP 1433
4060	"Cannot open database requested"	Login is valid but default database is offline or dropped	ALTER LOGIN [user] WITH DEFAULT_DATABASE = master;
10060	"Connection timed out"	Wrong IP/hostname, or SQL Server not accepting connections	Ping the server; verify SQL Server service is Running

Quick Connectivity Test

Before changing any SQL Server configuration, verify basic network connectivity:

PowerShell / Checklist

```
-- PowerShell: test TCP port 1433 from the client machine
Test-NetConnection -ComputerName SQLSERVER01 -Port 1433

-- Should return: TcpTestSucceeded : True
-- If False: firewall or SQL Server not listening on 1433

-- SQL Server Configuration Manager checklist:
-- 1. SQL Server (MSSQLSERVER) service = Running
-- 2. SQL Server Browser service       = Running (for named instances)
-- 3. TCP/IP protocol                  = Enabled
-- 4. TCP Port under IP All            = 1433
```

Named vs Default Instance

A default instance connects as SERVERNAME. A named instance connects as SERVERNAME\INSTANCENAME and requires SQL Server Browser. If Browser is stopped, named instance connections fail with error 53 even if the engine is running.

Login Failure — Error 18456

Error 18456 means "login failed." The state number reveals the exact reason.

STATE	MEANING
State 1	Generic — details suppressed for security. Check Error Log for real state.
State 2	Invalid user ID — login not found in sys.server_principals.
State 5	Invalid user ID — same as state 2 (older versions).
State 6	Login attempted with Windows auth but only SQL auth is configured.
State 7	Login disabled AND wrong password provided.
State 8	Correct login name but wrong password.
State 9	Login does not have permission to log in — login disabled.
State 11	Login valid but access denied to the server — check server role.
State 18	Password expired — must change at next login.
State 38	Login valid, but database is unavailable (offline, restoring, or dropped).

Always check the SQL Server Error Log for the actual state — client messages may show only State 1.

```
EXEC sp_readerrorlog 0, 1, 'Login failed', 'NovaMart';
```

Module 10: Basic Troubleshooting

4 / 7

Slide 4 of 7

Login Failure — Error 18456

Error 18456 means "login failed." The client always receives State 1 (generic, for security). The actual state code is written to the SQL Server Error Log. Always read the Error Log to find the real state before troubleshooting.

State	Meaning	Resolution
2	Login name not found in sys.server_principals	Create the login: CREATE LOGIN [name] WITH PASSWORD='...';
5	Same as State 2 (older SQL versions)	Create the login
6	Windows auth attempted but only SQL auth configured	Enable Windows auth: Server Properties → Security → Mixed Mode
7	Login disabled AND wrong password	ALTER LOGIN [name] ENABLE; reset password
8	Wrong password (login exists and is enabled)	Reset: ALTER LOGIN [name] WITH PASSWORD='newpass';
9	Login is valid but disabled	ALTER LOGIN [name] ENABLE;
11	Login valid but not authorized to log in to server	Grant CONNECT permission or add to a server role
18	Password expired — must change at next login	ALTER LOGIN [name] WITH PASSWORD='...' MUST_CHANGE = OFF;

38	Login valid but database unavailable (offline/restoring)	ALTER LOGIN [name] WITH DEFAULT_DATABASE = master;
----	--	--

Finding the Real State in the Error Log

T-SQL

```
-- Search the current error log for login failures
EXEC sp_readerrorlog 0, 1, 'Login failed';

-- Search for a specific login
EXEC sp_readerrorlog 0, 1, 'Login failed', 'LabSari';

-- The log shows: Login failed for user 'LabSari'. Reason: ... [State 9]
-- State 9 = login disabled → ALTER LOGIN LabSari ENABLE;
```

Client Error vs Server Log

The client application always sees: "Login failed for user 'X'. (Microsoft SQL Server, Error: 18456)" with State 1. The real diagnostic state is only in the SQL Server Error Log. Never try to resolve 18456 based on the client message alone.

Reading the SQL Server Error Log

The Error Log is the authoritative record of everything SQL Server has experienced.

VIA SSMS

- In Object Explorer: Management → SQL Server Logs
- Current log = most recent; Archive #1 = previous, etc.
- Double-click 'Current' to open Log File Viewer
- Filter by date range, error level, or search text
- Look for: Severity 16+ errors, stack dumps, I/O errors
- Event types: Information / Warning / Error
- Logs cycle at restart or when sp_cycle_errorlog is run

VIA T-SQL

```
-- Read current error log
EXEC sp_readerrorlog;

-- Search for a keyword
EXEC sp_readerrorlog 0, 1, 'error';

-- Read archive log #1
EXEC sp_readerrorlog 1, 1, 'Login failed';

-- Check log file location
EXEC xp_readerrorlog 0, 1, N'Logging SQL Server
messages';

-- Cycle the log (keeps current small)
EXEC sp_cycle_errorlog;
```

Critical errors to act on immediately: 823 (I/O failure), 824 (page checksum fail), 9001 (log not available).

Reading the SQL Server Error Log

The SQL Server Error Log is the authoritative record of everything the engine has experienced: startups, shutdowns, authentication failures, backup events, I/O errors, and stack dumps. It is always the first place to look during any incident.

Reading the Log in SSMS

- **Navigate** Object Explorer → Management → SQL Server Logs. "Current" is the active log. "Archive #1" is the previous.
- **Open** Double-click "Current" to open the Log File Viewer.
- **Filter** Use the Filter button to narrow by date range, message type, or search keyword.
- **Severity levels** Informational (normal), Warning (attention needed), Error (action required, Severity 16+).
- **Cycle log** Right-click SQL Server Logs → Configure → or run EXEC sp_cycle_errorlog to start a new log file.

Reading the Log via T-SQL

T-SQL

```
-- Read the current (active) error log
EXEC sp_readerrorlog;
```

```

-- Search for the keyword 'error' in the current log
EXEC sp_readerrorlog 0, 1, 'error';

-- Search archive log #1 for login failures
EXEC sp_readerrorlog 1, 1, 'Login failed';

-- Cycle the error log (keeps current log small)
EXEC sp_cycle_errorlog;

-- Check the log file path
EXEC xp_readerrorlog 0, 1, N'Logging SQL Server messages';

```

Critical Error Numbers to Act On Immediately

Error Number	Description	Action
823	I/O error reading from disk — hardware failure suspected	Take a backup immediately. Check storage hardware. Run DBCC CHECKDB.
824	SQL Server detected logical consistency-based I/O error	Take a backup immediately. Run DBCC CHECKDB. Escalate to storage team.
9001	Log file for database is unavailable	The database may be in suspect state. Check disk space and log drive health.
1205	Deadlock victim	Application-level — see Module 09. Capture deadlock graph if recurring.
17803	Insufficient memory to run server	Check max server memory setting and available RAM on the server.

Performance Bottlenecks — First Response

Narrow down to the right layer before tuning anything.

CPU Bottleneck

Symptoms: high CPU in Task Manager, high Batch Requests/sec, CXPACKET waits.

Quick checks: `sp_who2`, `dm_exec_requests ORDER BY cpu_time DESC`.

Common causes: missing indexes → table scans, implicit conversions, high MAXDOP.

Memory Bottleneck

Symptoms: high PAGEIOLATCH waits, low PLE (Page Life Expectancy < 300 sec).

Quick checks: `dm_os_sys_info`, `dm_os_buffer_descriptors`.

Causes: max server memory set too low, large unoptimised queries.

I/O Bottleneck

Symptoms: PAGEIOLATCH_SH/_EX waits, slow reads in Data File I/O chart.

Quick checks: `dm_io_virtual_file_stats`, DBCC SQLPERF('sys.dm_os_wait_stats').

Causes: storage latency, log drive contention, no SSD for log file.

Lock / Blocking Bottleneck

Symptoms: LCK_M_X waits, sessions stuck on 'SUSPENDED' status.

Quick checks: `dm_exec_requests WHERE blocking_session_id > 0`.

Causes: long open transactions, missing indexes causing wide table locks.

Network Bottleneck

Symptoms: ASYNC_NETWORK_IO waits, application-side latency despite fast queries.

Quick checks: `dm_exec_sessions` — check reads/writes vs elapsed time.

Causes: fetching large result sets, client-side slow row processing.

Query Design Bottleneck

Symptoms: high logical reads, Table Scan operators in execution plan.

Quick checks: `dm_exec_query_stats ORDER BY total_logical_reads DESC`.

Causes: missing covering indexes, SELECT *, outdated statistics.

Module 10: Basic Troubleshooting 6 / 7

Slide 6 of 7

Performance Bottlenecks — First Response

Narrow down to the correct layer before tuning anything. Each bottleneck type has characteristic symptoms, quick diagnostic queries, and common root causes.

Bottleneck	Symptoms	Quick Diagnostic	Common Cause
CPU	High CPU in Task Manager; CXPACKET waits; high Batch Requests/sec	<code>sp_who2</code> ; <code>dm_exec_requests ORDER BY cpu_time DESC</code>	Missing indexes → table scans; implicit type conversions; high MAXDOP
Memory	PAGEIOLATCH waits; low Page Life Expectancy (PLE < 300 sec)	<code>dm_os_sys_info</code> ; <code>dm_os_buffer_descriptors</code>	max server memory set too low; large unoptimised queries
I/O	PAGEIOLATCH_SH/_EX waits; slow reads in Data File I/O chart	<code>dm_io_virtual_file_stats</code> ; Activity Monitor Data File I/O	Storage latency; log and data files on same drive; no SSD for log
Locks	LCK_M_X waits; sessions stuck on SUSPENDED status	<code>dm_exec_requests WHERE blocking_session_id > 0</code>	Long open transactions; missing indexes causing wide table locks
Network	ASYNC_NETWORK_IO waits; fast queries but slow application response	<code>dm_exec_sessions</code> — reads/writes vs elapsed time	Fetching large result sets; client-side slow row processing

Query Design	High logical reads; Table Scan in execution plan	dm_exec_query_stats ORDER BY total_logical_reads DESC	Missing covering indexes; SELECT *; outdated statistics
--------------	--	---	--

i

PLE (Page Life Expectancy)

PLE measures how long (in seconds) a data page stays in the buffer pool before being evicted. PLE < 300 seconds historically indicated memory pressure. On modern servers with large RAM, PLE should be much higher (thousands of seconds). Monitor the trend over time rather than using a fixed threshold.

LAB 10

Monday Morning — 3 Support Tickets

Duration: ~40 min · Tool: SSMS + Configuration Manager · Instance: local

Ticket 1: 'Cannot connect to SQL Server'

Simulate: stop SQL Server Browser service → attempt named instance connection
 Diagnose: check service status in Config Manager
 Resolve: restart SQL Server Browser → reconnect

Ticket 2: 'Login failed for user LabSari'

Simulate: disable login LabSari (ALTER LOGIN LabSari DISABLE)
 Diagnose: read Error Log → identify state number
 Resolve: ALTER LOGIN LabSari ENABLE → verify login works

Ticket 3: 'The report query is very slow today'

Simulate: run SELECT * FROM Employee without WHERE clause (large result)
 Diagnose: Activity Monitor → Recent Expensive Queries → view execution plan
 Resolve: add WHERE clause or proper filter → compare elapsed time

Validation: all 3 tickets resolved, root cause identified, and steps documented in a comment block in SSMS.

Module 10: Basic Troubleshooting 7 / 7

Slide 7 of 7

Lab 10: Monday Morning — 3 Support Tickets

Goal	Duration	Tool	Instance
Simulate and resolve three realistic connection, login, and query support tickets	~40 min	SSMS + Config Manager	Local SQL Server

Prerequisites

- SQL Server instance running with NovaMart database.
- Login LabSari exists (created in Lab 05) or create it: `CREATE LOGIN LabSari WITH PASSWORD='P@ssw0rd';`

Ticket 1: "I cannot connect to SQL Server"

Simulate: Open SQL Server Configuration Manager. Stop the SQL Server Browser service.

- In SQL Server Configuration Manager → SQL Server Services → right-click SQL Server Browser → Stop.

Expected: SQL Server Browser shows Stopped.

- In SSMS, try to connect to the named instance (SERVERNAME\SQLEXPRESS or similar) using the full instance name.

Expected: Connection fails with error 53 or "network path not found".

3. Diagnose: In Config Manager, confirm SQL Server Browser is Stopped. This is the root cause for named instance discovery.

Expected: Root cause identified: SQL Server Browser stopped.

4. Resolve: Right-click SQL Server Browser → Start. Retry the connection in SSMS.

Expected: Connection succeeds.

Ticket 2: "Login failed for user LabSari"

Simulate: Disable login LabSari.

5. In SSMS, run: ALTER LOGIN LabSari DISABLE;

Expected: Command succeeds.

6. Try to connect to SSMS using LabSari credentials (SQL Server Authentication). Note the error message.

Expected: Error 18456 — Login failed for user 'LabSari'.

7. Read the Error Log to find the real state:
EXEC sp_readerrorlog 0, 1, 'Login failed', 'LabSari';

Expected: Log entry shows: State 9 (login disabled).

8. Resolve: ALTER LOGIN LabSari ENABLE;

Expected: Login succeeds when retried with LabSari credentials.

Ticket 3: "The report query is very slow today"

Simulate: Run a query without a useful WHERE clause.

9. Enable Include Actual Execution Plan (Ctrl+M). Run:
SELECT * FROM dbo.Employee ORDER BY FirstName;

Expected: Query completes; execution plan appears in the Execution Plan tab.

10. In the execution plan, identify the most expensive operator (Table Scan or Clustered Index Scan). Note the cost %.

Expected: Table Scan or similar full-scan operator with highest cost % is visible.

11. Check Activity Monitor → Recent Expensive Queries to see if the query appears.

Expected: The full-scan query appears in the expensive queries list.

12. Resolve by adding a WHERE clause: SELECT * FROM dbo.Employee WHERE DeptID = 1;
Compare execution time.

Expected: Fewer rows returned; elapsed time reduced. Execution plan shows index seek (if index exists on DeptID).

Validation Checklist

- ☐ Ticket 1: connection failure simulated, SQL Server Browser identified as root cause, connection restored
- ☐ Ticket 2: login failure simulated, Error Log reveals State 9, login re-enabled and access confirmed
- ☐ Ticket 3: slow query identified in execution plan, WHERE clause applied, performance improved
- ☐ All three root causes documented (simulated incident notes)

Troubleshooting the Lab

Symptom	Likely Cause	Resolution
Connection still fails after Browser start	Default instance — Browser not needed	Default instances connect without Browser; use SERVERNAME (no backslash)
LabSari login does not exist	Login was not created in Lab 05	CREATE LOGIN LabSari WITH PASSWORD='P@ssw0rd', DEFAULT_DATABASE=master;
State 9 not visible in Error Log	Log has been cycled	Try Archive log #1: EXEC sp_readerrorlog 1, 1, 'Login failed', 'LabSari';
